

Managing Perl Modules

Install Perl modules required by CGI scripts on your account.

If you run Perl or CGI scripts, you may need additional Perl modules installed in your user environment.

Install a Perl module

1. Go to **System Info & Files → Perl Modules**.
2. Search for the module name (for example `JSON` or `LWP::UserAgent`).
3. Select the module and click install.
4. Wait for installation to complete.

Verify installation

Run a test script that uses the module, or execute `perl -MModule::Name -e 'print "OK "'` from the terminal. Some modules require server-level installation — contact DanumHost support if the module is unavailable in the installer.
